

Abstract

The present invention provides an excellent drug delivery system to posterior segments of the eye. An injection according to the present invention is a subconjunctival injection which comprises fine particles containing a drug and enables the drug to deliver to the posterior segments of the eye. The drug can be efficiently delivered to the posterior segments of the eye (such as a retina, a choroid and an optic nerve) while scarcely injuring ophthalmic tissues by administering the fine particles containing the drug subconjunctivally. Preferred fine particles are made of a synthetic biodegradable polymer, their average particle diameter is 50 nm to 150 μ m, and the drug is dispersed in the fine particles uniformly. Preferred drugs are anti-inflammatory, immunosuppressors, antivirals, anticancer drugs, angiogenesis inhibitors, optic neural protectants, antimicrobials and antifungal agents.
